What can we do with suffix tree?

Linear algorithms for exact string matching

like KMP

Search for strings

- Check if a string P of length m is a substring in O(m) time.
- Find all z occurrences of the patterns P_1, \dots, P_q of total length m as substrings in O(m+z) time.
- Search for a regular expression P in time expected sublinear in n.
- Find for each suffix of a pattern P, the length of the longest match between a prefix of $P[i \dots m]$ and a substring in D in $\theta(m)$ time.
- **⑤** ...

Find properties of the strings

- Find the longest common substrings of the string S_i and S_j in $\theta(n_i + n_j)$ time.
- **②** Find all maximal pairs, maximal repeats or supermaximal repeats in $\theta(n+z)$ time, if there are z such repeats.
- **)** Find the Lempel-Ziv decomposition in $\theta(n)$ time .
- Find the longest repeated substrings in $\theta(n)$ time.
- **Solution** Find the most frequently occurring substrings of a minimum length in $\theta(n)$ time.
- **③** Find the shortest strings from Σ that do not occur in D, in O(n+z) time, if there are z such strings.
- Find the shortest substrings occurring only once in $\theta(n)$ time.
- § Find, for each i, the shortest substrings of S_i not occurring elsewhere in D in $\theta(n)$ time.
- **②** ...

Trie, Radix Tree, Suffix Trie & Suffix Tree

 $trie^1$ (AKA prefix tree) is a dictionary tree.

- stores a set of words.
- each node represents a character except that root is empty string.
- words with common prefix share same parent nodes.
- minimal deterministic finite automaton that accepts all words.

radix tree (AKA patricia trie or radix trie) is a trie with compressed chain of nodes.

• Each internal node has at least 2 children.

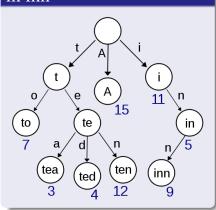

suffix trie is a trie which stores all suffix of a given string. suffix tree is a suffix radix tree.

 that enables linear time construction and fast algorithms of other problems on a string.

¹pronounced as in word retrieval by its inventor, /tri:/ "tree", but pronounced /traɪ/ "try" by other authors

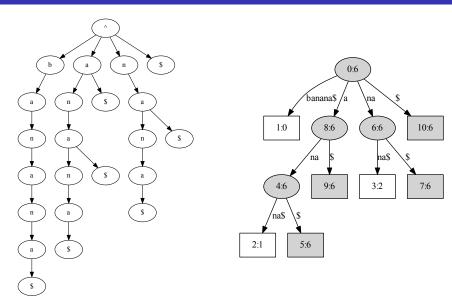

Trie & Radix Tree

Trie of "A to tea ted ten i in inn"

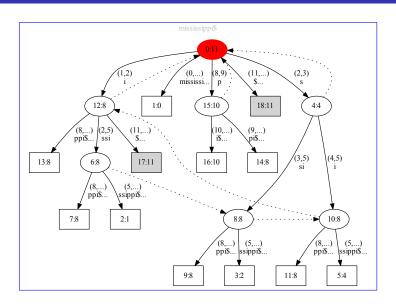

Radix tree example romane romanus romulus rubens ruber rubicon rubicundus ulus undus

Suffix Trie & Suffix Tree of "banana"

Suffix Tree of "mississippi"

History of Suffix Tree Algorithms

- First linear algorithm was introduced by Weiner 1973 as position tree. Awarded by Donald Knuth as "Algorithm of the year 1973".
- Greatly simplified by McCreight 1976.

Above two algorithms are processing string backward.

• First online construction by Ukkonen 1995, which is easier to understand.

Above algorithms assume size of alphabet as fixed constant.

• Limitation was break by Farach 1997, optimal for all alphabets.

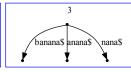

Further study are continued to scale to scenarios when the whole suffix tree or even input string cannot fit into memory.

Backward Construction of Suffix Tree

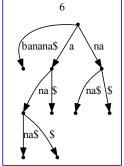

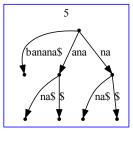

10 / 25

Construct Suffix Tree by Sorting Suffix

```
Suffix:
              Sorted suffix:
                             Tree of sorted suffix:
                             |-i->|-
mississippi
                               |-ppi
ississippi
              ippi
                                   |-ssi->|-ppi
ssissippi
              issippi
sissippi
              ississippi
                                           |-ssippi
              mississippi
issippi
                             |-mississippi
                             |-p->|-i
ssippi
              рi
                              |-pi
sippi
              ppi
                             |-s->|-i-->|-ppi
ippi
              sippi
                                   | |-ssippi
ppi
              sissippi
                                   |-si->|-ppi
рi
              ssippi
                                          |-ssippi
              ssissippi
```

Time complexity will be $O(N^2 \log N)$. Space complexity will be $O(N^2)$.

Naïve Algorithm

```
SUFFIXTREE(string)
    for i \leftarrow 1 to length(string)
          do UPDATE(tree_i) \triangleright Phrase i
UPDATE(tree_i)
    for i \leftarrow 1 to i
          do node \leftarrow tree_i.FIND(suffix[j \text{ to } i-1])
              EXTEND(node, string[i]) \triangleright Extension j
```

Time complexity will be $O(N^3)$.

Space complexity will be $O(N^2)$.

The challenge is to make sure $tree_i$ is updated to $tree_{i+1}$ efficiently.

Suffix Extend Cases of Naïve Algorithm

Case I If path $S_{j...i}$ ends at leaf, append a char S_{i+1} to end of edge into leaf.

 $S_{i...i+1} = \dots nan$

 $S_{i...i+1} = ... nay$

Case II If path $S_{j...i}$ ends in the middle of an edge, and next char S_{i+1} is not equal to the next char in the edge, split that edge, create a internal node, add a new edge to a new leaf.

Case III If path $S_{j...i}$ ends in the middle of an edge, and next char S_{i+1} is equal to the next char in the edge, do nothing, extension has done.

$$S_{j...i} = ...na$$

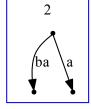

$$S_{j...i+1} = \dots nan$$

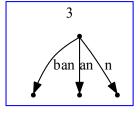

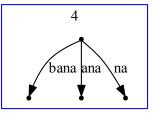

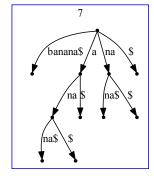

Naïve Online Construction of Suffix Tree

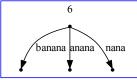

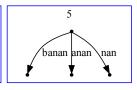

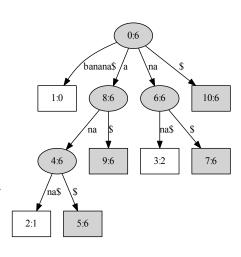

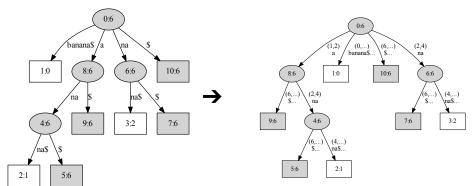

Properties of Suffix Tree

- Each update will add exactly 1 leaf node.
 - $nr_leaf = N$
- Suffix tree is full tree.
 - Each internal node has at least 2 children.
 - nr_internal < N
 - $nr_node < 2N$
- Worst case Fabonacci word
 - abaababaabaab
- Suffix is either explicit or implicit.
 - Explicit when it ends at a node.
 - Implicit when it ends in the middle of an edge.

Optimization of Naïve Algorithm

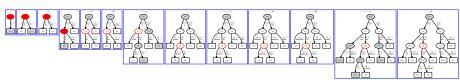

- Substrings can be represented as (start, end) pair of their index in orignal string.
 - Reduce space complexity to O(N) if size of alphabet is fixed constant.
- Once a leaf, Always a leaf
 - Represent edge that links to a leaf as (start, \cdots).
 - Extend leaf nodes for free. We do not need Extend Case I.

jc-yang (Osaka-U) SuffixTree November 16, 2011

Active Point

- During a phrase, if we meet Extend Case III, that is if we found S[i+1] already exists in suffix[j...i] then S[i+1] will exists in $\forall suffix[k...i], k \in j...i$.
- Thus Case III is a sign that means update of this phrase is finished.
- During phrase i if we stopped at suffix[k ... i] by Case III, then in next phrase we can start from suffix[k ... i + 1] because all suffix start with 1 ... k 1 will end at Case I.
- We called this point(current internal node, current position *k* in string) as Active Point.

18 / 25

Ukk's Update using Active Point

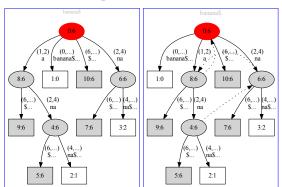

```
UPDATE(tree_i)
     current\_suffix \leftarrow active\_point
     next \ char \leftarrow string[i]
 3
     while True
          do if there exists edge start with next_char
 4
 5
                 then break

    Case III

 6
                 else
                       split current edge if implicit
                       create new leaf with new edge labelled next_char
 9
              if current suffix is empty
                 then break
10
                 else current\_suffix \leftarrow next shorter suffix
11
12
     active\_point \leftarrow current\_suffix
```

Suffix Link to find next shorter suffix

- Suffix link
 - Internal node of suffix $X\alpha$ has a link to node α .
 - If α is empty, suffix link points to root.
- How to create suffix link
 - Link together every internal nodes that are created by splitting in same phrase.

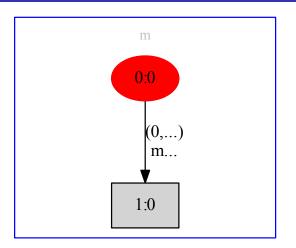

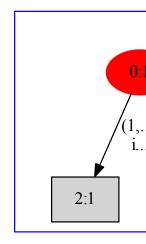

20 / 25

Fast jump using Suffix Link

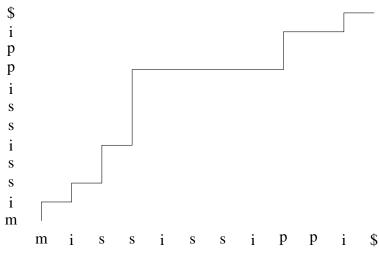

- Assume we are at Suffix $X\alpha\beta$, whose parent internal node represent $X\alpha$.
 - Go back to parent internal node,
 - 2 Jumping follow the node's suffix link to the node represent Suffix α
 - **1** Go down to Suffix $\alpha\beta$.
- Even jump down in step 3 because we already know length of β . (Skip/Count trick)
- Combining all these tricks we can Extend a character in O(1) time.

Experiment – mississippi

Time Complexity Analysis

Time complexity is 2N = O(N).
